Abstract

The scope of this study was to discover the association between facial expressions of students in an academic lecture and the level of comprehension shown by their expressions. This study focused on finding the relationship between the specific elements of learner's behavior for the different emotional states and the relevant expression that could be observed from individual students. The experimentation was done through surveying quantitative observations of the lecturers in the classroom in which the behavior of students are recorded and were statistically analyzed. The main aim of this paper is to derive association rules that represent relationships between input conditions and results of domain experiments. Hence the relationship between the physical behaviors that are linked to emotional state with the student's comprehension is being formulated in the form of rules. We present Predictive Apriori algorithm that is able to find all valid class association rules with high accuracy. The rules derived by Predictive Apriori are pruned by objective and subjective measures.

Index terms— class association rules, predictive apriori algorithm, pruning, facial expression, objective measure, subjective measure.

1 Introduction

oday's learning community focus on the vision of faculty and students working collaboratively towards deep, meaningful, high quality learning. The achievements of digital communication lead learning communities into a new dimension. There is an increase in virtual schools worldwide as education mediated by computer is considered very important for the future [12]. Nowadays, Learning Management Systems (LMS) are being installed more and more by universities, community colleges, schools, businesses, and even individual instructors in order to add web technology to their courses and to supplement traditional face-to-face courses [10]. LMS systems accumulate a vast amount of information which is valuable for analyzing the students' behavior and could create a gold mine of educational data [7].

Teacher student Interaction plays a vital role in the classroom environment. [5] In the classroom, lecturers and students both consciously and students' behavior and could create a gold mine of educational data [7].

Teacher student Interaction plays a vital role in the classroom environment. [5] In the classroom, lecturers and students—both consciously and unconsciously—send and receive nonverbal cue several hundred times a day. Lecturers should be aware of nonverbal communication in the classroom for two basic reasons: to become better receivers of student's messages and to gain the ability to send positive signals that reinforces students' learning. Lecturers should be skilled at avoiding negative signals that stifle their learning.

Studies have evaluated that student emotional states are expressed with specific behaviors that can be automatically detected [17]. A preliminary study, carried out as the first part of this research, proved that the communicative impact of the face is so powerful in interaction. The most expressive way students display emotions is through facial expressions. Facial expressions are the primary source of information, next to words,

3 B) CLASS ASSOCIATION RULES

44 in determining the student's emotional feelings to express their comprehension. It also strongly recommends that
45 there is a direct connection between the facial expressiveness of the students and their level of comprehension.
46 Momentary expressions that signal emotions include muscle movements such as raising the eyebrows, wrinkling
47 the forehead, shrinking or enlarging the eyes or curling the lip [9].

48 This research specifically focused on studying the relationship between facial expressions of the students in an
49 academic lecture and the level of comprehension shown by their expressions. The aim was to identify physical
50 behaviors that are linked to emotional states, and to identify how these emotional states are linked to student's
51 comprehension. The significance of the study was statistically interpreted. Hence it derives the Association
52 rules which show the relationship between facial expressions of students in an academic lecture and the level of
53 comprehension shown by their expressions.

54 2 Concepts a) Association Rule Mining

55 Data mining is the analysis of observational data sets to find the relationships among the data and to summaries
56 it in novel ways that are both understandable and useful to the data owner [4]. The mining of association rules
57 is a typical data mining task that works in an unsupervised manner. A major advantage of association rules
58 is that they are theoretically capable of revealing all interesting relationships, called associations. It discovers
59 relationships among attributes, producing if-then statements concerning attribute-values [1]. An association rule
60 $X \Rightarrow Y$ transactions where X occurs; there is a high probability of having Y as well. X and Y are called respectively
61 the antecedent and consequent of the rule. The strength of such a rule is measured by its support and confidence.
62 The confidence of the rule is the percentage of transactions with X in the dataset that contain the consequent Y
63 also. The support of the rule is the percentage of transactions in the dataset that contain both the antecedent
64 and the consequent.

65 Definition of Association Rule: Let $I = \{i_1, i_2, \dots, i_m\}$ be set of items, D be task relevant data of transactions, T
66 be each transaction, a set of items, such that $T \subseteq I$ where \subseteq denotes proper subset and TID be the Transaction
67 Identifier. An Association Rule is defined as an implication of type $A \Rightarrow B$, where $A \subseteq I$, $B \subseteq I$ and $A \cap B = \emptyset$
68 support S , where C : Confidence ($A \Rightarrow B$) = $P(A \cup B) / P(A)$, S : Support ($A \Rightarrow B$) = $P(B | A)$ where P is probability.
69 [20] If B be a dataset with n items, then the support of an item set X is the number of instances which satisfy X
70 given by the formula: $|\{t \in B \mid X \subseteq t\}| / n$ (1)

71 The confidence of an association rule is a percentage value that shows how frequently the consequent part
72 occurs among all the groups containing the rule antecedent part:

$$73 \text{Confidence} = \frac{|\{t \in B \mid X \subseteq t \text{ and } Y \subseteq t\}|}{|\{t \in B \mid X \subseteq t\}|} \quad (2)$$

74 Association rule mining has been applied to e-learning systems for traditional association analysis (finding
75 correlations between items), such as discovering interesting relationships from student's usage information in
76 order to provide feedback to course author [11], finding out the relationships between each pattern of learner's
77 behaviour [18] etc. Association rule mining also has been applied to the learning of sequential patterns mining,
78 which is a restrictive form of association rule mining in the sense that not only the occurrences themselves,
79 but also the order between the occurrences of the items is taken into account. The extraction of sequential
80 patterns has been mainly used in e-learning for evaluating the learners' activities and can be used in adapting
81 and customizing resource delivery [19]; discovering and comparison with expected behavioural patterns specified
82 by the instructor that describes an ideal learning path [8]; classification [2].

83 Classification using association rules combines association rule mining and classification, and is therefore
84 concerned with finding rules that accurately predict a single target (class) variable. The key strength of
85 association rule mining is that all interesting rules are found. The number of associations present in even
86 moderate sized databases can be, however, very large - usually too large to be applied directly for classification
87 purposes. Therefore, any classification learner using association rules has to perform three major steps: Mining
88 a set of potentially accurate rules, evaluating and pruning rules, and classifying future instances using the found
89 rule set.

90 3 b) Class Association Rules

91 Normal association rule mining does not have any target. It finds all possible rules that exist in data, i.e., any
92 item can appear as a consequent or a condition of a rule. However, in some applications, the user is interested in
93 some targets. Let T be a transaction data set consisting of n transactions. Each transaction is also labeled with
94 a class y . Let I be the set of all items in T , Y be the set of all class labels and $I \cap Y = \emptyset$. A class association rule
95 (CAR) is an implication of the form $X \Rightarrow y$, where $X \subseteq I$, and $y \in Y$. The definitions of support and confidence
96 are the same as those for normal association rules.

97 A class Association rule is defined to be an implication with a pre-specified target (a value of target attribute)
98 as its consequence and its support and confidence are above given thresholds from a dataset respectively. Given
99 a target attribute, minimum support σ and minimum confidence δ , a complete class association rule set is a set
100 of all class association rules, denoted by $Rc(\sigma, \delta)$.

101 Conceptually, class association rules differ from standard association rules in their consequence. The objective
102 is to generate the complete set of class association rules that satisfy the minimum support as well as the minimum
103 confidence constraints and to build a classifier from the class association rule set. To this aim, one combines the

104 prediction of all rules which satisfy the example: if there is only one rule, the consequent of this rule is taken to
105 be the predicted class for the example; if there is no rule satisfying the example, then a default class is taken to
106 be the The Rule hold in D with confidence C and predicted class; and if there are multiple rules satisfying the
107 example, then their predictions must be combined.

108 Our goal is to find the minimum subset of the complete class association rule set that has the same prediction
109 power as the complete association rule set [6].

110 4 C) Pruning

111 Association rule mining algorithms normally discover a huge quantity of rules and do not guarantee that all the
112 rules found are relevant [3]. Support and confidence factors can be used for obtaining interesting rules which
113 have values for these factors greater than a threshold value. Although these two parameters allow the pruning
114 of many associations, another common constraint is to indicate the attributes that must or cannot be present
115 in the antecedent or consequent of the discovered rules. Hence the solution is to evaluate, and post-prune the
116 obtained rules in order to find the most interesting rules for a specific problem. A pruning technique is used for
117 removing redundant or insignificant rules.

118 For practical applications the number of mined rules is usually too large to be exploited entirely. This is why
119 the pruning phase is more essential in order to build accurate and compact classifiers. The smaller the number
120 of rules a classifier needs to approximate the target concept satisfactorily and the human can interpret the result
121 easily. Pruning strategies try to close the gap between the mining of a large number of class association rules
122 and a small and powerful set of classification rules. Hence Pruning is an imperative step in mining association
123 rules which helps in accurate classification.

124 5 III.

125 6 Methods

126 In this research a study was conducted for observing the facial expressions of the students in academic lecture-
127 environments. The scope of this study was to establish whether there is a relationship between the student's facial
128 expressions and the comprehension of the students. Also to examine whether facial expression of the students is
129 a tool for the lecturer to interpret comprehension level of students in virtual classroom.

130 In order to perform the experiment for the study, survey was taken using stratified sampling technique with a
131 questionnaire. Questionnaire was given to 100 Lecturers from 10 academic institutions, and their responses were
132 collected. It focuses on the role of facial expressions in non-verbal communication. It ranks the order in which
133 the lecturer interprets the level of comprehension in the classroom through various nonverbal communication
134 modes. It also measures the frequency of the expressions exhibited by the action units of face for the purpose
135 of communication. Finally, how the expressions are correlated with the emotions of the students was analyzed.
136 Experimental data in the domain is integrated into a dataset after statistical interpretation to serve as the basis
137 for analysis.

138 The goal of association rule mining is to find all rules satisfying some basic requirement such as minimum
139 support and the minimum confidence. A set of association rules for the purpose of classification is called predictive
140 association rule set. Predictive association rules are based on attribute values where the consequences of rules are
141 pre-specified categories. A class association rule set is a subset of Predictive association rules with the specified
142 targets (classes) as their consequences [6]. Hence mining predictive association rules undergoes the following two
143 steps. Find all class association rules.

144 Prune and organize the found class association rules and return a sequence of predictive association rules.
145 Here in this paper all the class association rules are derived by Predictive Apriori Algorithm and the derived
146 rules are pruned by objective and subjective measures.

147 7 a) Mining Class Association Rules

148 The mining of association rules is a typical data mining task that works in an unsupervised manner. A major
149 advantage of association rules is that they are theoretically capable of revealing all interesting relationships in a
150 set of data.

151 The improved version of the Apriori algorithm is the Predictive Apriori algorithm [13], which automatically
152 resolves the problem of balance between two parameters, maximizing the probability of making an accurate
153 prediction for the dataset. In order to achieve this, a parameter called the exact expected predictive accuracy is
154 defined and calculated using the Bayesian method [15], which provides information about the accuracy of the
155 rule found. In this way the user only has to specify the maximal number or rules to discover.

156 Apriori mines considerably more rules than predictive Apriori but most of them are pruned in the final set of
157 classification rules. The advantage of predictive Apriori is that it generates fewer rules right from the start [14].

158 8 b) Predictive Apriori Algorithm

159 The Predictive Apriori algorithm [13] generates frequent item sets, but it uses a dynamically increasing minimum
160 support threshold. It searches with an increasing support threshold for the best rules concerning a support-based

161 corrected confidence value. A rule is added if: the expected predictive accuracy of this rule is among the "n" best
 162 and it is not subsumed by a rule with atleast the same expected predictive accuracy. 5. Determine all frequent
 163 item sets whose support value is greater than the support threshold. 6. With such frequent item sets generate
 164 rules with high predictive accuracy. 7. Select the strong rules and include them in R. 8. Repeat the generation
 165 of rules till you get the desired number of association rules. 9. Output the optimal class association rule set
 166 R. 10. An important improvement in the Predictive Apriori (PA) is that there is no need to specify any of the
 167 parameters. Its objective is to find the best N association rules, being N a fixed number. An optimum set of
 168 class association rules are the output of this algorithm.

169 9 c) Predictive Accuracy

170 The Predictive Apriori algorithm differs from standard apriori in such a way that it employs a different measure
 171 of interesting of an association rule [14]. Predictive apriori evaluates the confidence of rules depending on their
 172 support. Its measure of interestingness is to maximize the expected accuracy an association rule will have on
 173 unseen data. This suits the requirements of the classification task we want to perform afterwards.

174 Scheffer [13] uses a Bayesian framework to calculate the predictive accuracy out of the support and confidence
 175 of a rule. In doing so the support is a rough guideline of how much we should mistrust the confidence. The
 176 higher the support, the more the confidence converges to the expected accuracy on future data.

177 This algorithm uses the Bayesian method to propose a solution that quantifies the expected predictive accuracy
 178 of an association rule with a given confidence and the support of the rule's body (left side of the rule). Scheffer
 179 [13] defines predictive accuracy as: Let $X \rightarrow Y$ is an association rule. The predictive accuracy, $C(X \rightarrow Y) = \Pr(r$
 180 satisfies $Y \mid r$ satisfies $X)$ is the conditional probability of $Y \mid r$ given that $X \mid r$ when the distribution of r (records)
 181 is governed by $P(\text{Process})$. The confidence $\text{conf}(X \rightarrow Y)$ of the association rule $X \rightarrow Y$ is the relative frequency of
 182 the predictive accuracy in the data. Hence the confidence value is optimistically biased if one wants to use it for
 183 a predictive task.

184 The predictive accuracy describes whether the predicted values match the actual values of the target field due
 185 to statistical fluctuations and noise in the input data values. Hence it refers the ability of the model to correctly
 186 predict the class label of new or previously unseen data.

187 Using Bayesian formula the expected accuracy E of a rule $r, X \rightarrow Y$ given its confidence conf and the support
 188 of the rule body $s(X)$ is calculated as $E(c(r) \mid \text{conf}(r), s(X)) = \frac{c(r) \cdot s(X)}{c(r) + (1 - c(r)) \cdot s(X)}$ (3)

189 This equation calculates the expected accuracy over unseen instances given the support of the rule body and
 190 the confidence of the rule, given that the instances are independent and identically distributed. This expectation
 191 value is called predictive accuracy.
 192

193 10 d) Pruning

194 Traditionally for Pruning, [16] the use of objective interesting measures such as Predictive accuracy, support and
 195 confidence, Laplace, chi-square statistic, correlation coefficient, Entropy gain, Gini index, conviction, etc can be
 196 used for ranking the obtained rules in order. Subjective measures can also be used based on subjective factors
 197 controlled by the user. The subjective approaches involve user participation in order to express, in accordance
 198 with his or her previous knowledge, which rules are of interest so that the user can select the rules with highest
 199 values in the measures that he/she is more interested. The number of rules can be decreased by only applying
 200 these objective and subjective measures.

201 In this paper the class association rules derived by Predictive Apriori are pruned by applying the objective
 202 measure, Accuracy Rule Ranking followed by the subjective measure Expert Domain Knowledge. e) Pruning using
 203 Objective Measure For Pruning using objective measure, the obtained class association rules are to be ranked first.
 204 The ranking of class association rules can be done using the objective measure of interestingness. Predictive apriori
 205 considers predictive accuracy for ranking and so it sorts rules according to their predictive accuracy. Threshold
 206 accuracy is considered and the rules with predictive accuracies below the threshold accuracy will be pruned. f)
 207 Pruning using Subjective Measure However, the rules discovered by Predictive Apriori Algorithm and pruned by
 208 Accuracy Rule Ranking method may not all be useful with respect to the domain. Hence it is essential to prune
 209 the rules guided by Expert domain knowledge. Also, some interesting rules may not be found from experimental
 210 data. Thus it is advisable to extend the Association Analysis to other sources such as the related literature in
 211 the domain, to enhance the Knowledgebase.

212 Prior experience and domain knowledge [3] of the persons play an important role in ranking the rules. Steps
 213 to Prune using Basic Domain Knowledge

214 11 Consider rules derived using the Predictive Apriori

215 Algorithm which is ranked by objective measure. 2. Use domain expert opinion to determine obvious and
 216 uninteresting rules. 3. If a derived rule matches an obvious rule or identified as uninteresting, then prune the
 217 derived rule. 4. Store obvious rules in a rule base for future use.

218 These represent interesting information. 5. Repeat this process until all rules discovered are considered
 219 interesting in the domain.

220 Before running the class association rule mining algorithm, the relevant knowledgebase on the dataset in
221 accordance with statistical interpretation associated with expert's response have to be prepared. In the context
222 of Virtual educational environments, we can identify some common attributes that is observed from the students
223 as seen in table1. Attributes are evaluated and ranked using Gain Ranking Filter in Weka. Ranking exhibits
224 the extent of the attribute in expressing the comprehension level. Finally, we use the knowledgebase as a basis
225 of rule repository in which subjective analysis is performed and associations are identified to discover the rules.
226 In this context the use of standard metadata about the action units represent the facial expressions of students
227 and allows the creation and maintenance of a common knowledge base with a common vocabulary as shown in
228 Table1.

229 12 IV.

230 13 Experimental Results

231 Experimental data in the domain is integrated into a dataset to serve as the basis for analysis. On analyzing
232 the experimental data, association between facial expressions of students in an academic lecture and the level
233 of comprehension shown by their expressions could be observed and the rules that were sufficient to answer any
234 question with respect to the problem domain could be derived. Using the statistical measure of interestingness
235 such as correlation and mean on the attributes, data is cleaned, grouped and categorized to form a dataset as
236 shown in Table2 as good data preparation is the key to produce valid and reliable model.

237 Prior Experiments and statistical analysis on this research strongly suggested that facial expression is the
238 most frequently used nonverbal communication mode used by the students in the classroom and student's
239 expressions are significantly correlated to their emotions which can help to recognize their comprehension in the
240 lecture. In particular, the more expressive the student is, more the lecturer recognizes the comprehension of the
241 students. Facial Expressions that signal emotions include muscle movements such as raising eyebrows, wrinkling
242 the forehead, rolling the eyes or curling the lip. So the action units of face such as eyes, mouth, eyebrow and
243 forehead are the emotion indicators. Here we analyzed whether the emotional feelings of the students with respect
244 to comprehension are indicated through expressions of facial action units. Experiments were made with survey
245 and analysis was done through SPSS.

246 In order to find the association between the facial expressions of students in an academic lecture and the level
247 of comprehension shown by their expressions, Predictive apriori algorithm is applied on the above dataset and
248 the class association rules are being derived using Weka tool.

249 The discovered rules are sorted and ranked according to their Predictive accuracy. Irrespective of the number
250 of rules to be predicted set as 100, Objective pruning got the optimal number of rules by applying the threshold
251 accuracy 0.46584 as shown in Table4. Hence the number of class association rules generated was 14 as shown in
252 Table3. For further simplification of rules subjective pruning was done on the pruned rules to get the best optimal
253 set of rules. The obtained results or rules are interpreted and evaluated by the domain expert's knowledge for
254 further actions. Rules with similar Predictive accuracies are grouped and some interesting rules that may not
255 be found from experimental data are identified and included. The final objective is to put the results into use
256 in form of if-then rules as shown below. Lecturers use the above discovered rules for making decisions about the
257 comprehension of the student in the virtual classrooms in order to improve the student's learning.

258 These interesting Class Association Rules are useful for predictive analysis and are used to populate a
259 knowledgebase. They represent the knowledge that a domain expert discovers on learning from experimental
260 data and literature surveys which can be used for decision support and classification.

261 V.

262 14 Conclusion

263 Recent research tells teachers and students use facial expressions to form impressions of another. Facial Expression
264 plays a vital role in identification of Emotions and Comprehension of the students in the virtual classrooms.
265 This study derived the association between the specific elements of learner's behaviour for the different emotional
266 states and the relevant expression that could be observed from individual students. This paper derived association
267 rules that represent the relationship between the physical behaviors that are linked to emotional state with the
268 student's comprehension and it was being formulated in the form of rules. The effectiveness of this method
269 will be improved by correlating more features from different action units of the face which would improve the
270 classification process. ¹
